

1.What does this code do?

The dictionary temperatures contain four Fahrenheit samples for each of five days.
What does the “for” statement do?

```
temperatures = {  
    'Monday': [67, 71, 74, 77],  
    'Tuesday': [52, 56, 66 , 50],  
    'Wednesday': [77, 80, 87 , 95],  
    'Thursday': [67, 77, 81 , 77],  
    'Friday': [54 , 60 , 67, 60],  
}  
  
for k, v in temperatures.items():  
    print(f'{k}: {sum(v)/len(v):.0f}')
```

The for statement above loops through each key and sums the values and then divides by the number of values to get an average for each key/day of the week.
