

The datetime module provides a number of class types to deal with dates, times, and time intervals with a more object-oriented interface. Please list the main object class types and explain their usage.

1. date - This is used for specific dates. Examples are: Halloween, birthdays, and other holidays. The format is year, month, day.
2. time - This is used for specific times like midnight or an alarm. The format is hour, minute, second, microsecond.
3. datetime - This combines date and time. The format is year, month, day, hour, minute, second, microsecond.
4. timedelta - this is for time spans. You can use it to tell you time until an event or time since an event has passed. You can use timedelta to tell you the difference between datetime objects.
